Lecture 3: Performance/Power, MIPS Instructions

• Today’s topic:
  - More performance/power equations, examples
  - MIPS instructions

• HW1 is due on Thursday (+ 1.5 days)

• TA office hours (CADE Lab, TA queue)
A Primer on Clocks and Cycles
Performance Equation - I

CPU execution time = CPU clock cycles $\times$ Clock cycle time
Clock cycle time = $\frac{1}{\text{Clock speed}}$

If a processor has a frequency of 3 GHz, the clock ticks 3 billion times in a second – as we’ll soon see, with each clock tick, one or more/less instructions may complete.

If a program runs for 10 seconds on a 3 GHz processor, how many clock cycles did it run for?

If a program runs for 2 billion clock cycles on a 1.5 GHz processor, what is the execution time in seconds?
Performance Equation - II

CPU clock cycles = number of instrs \times \text{avg clock cycles per instruction (CPI)}

Substituting in previous equation,

Execution time = \text{clock cycle time} \times \text{number of instrs} \times \text{avg CPI}

If a 2 GHz processor graduates an instruction every third cycle, how many instructions are there in a program that runs for 10 seconds?
Factors Influencing Performance

Execution time = clock cycle time x number of instrs x avg CPI

• Clock cycle time: manufacturing process (how fast is each transistor), how much work gets done in each pipeline stage (more on this later)

• Number of instrs: the quality of the compiler and the instruction set architecture

• CPI: the nature of each instruction and the quality of the architecture implementation
Example

Execution time = clock cycle time x number of instrs x avg CPI

Which of the following two systems is better?

• A program is converted into 4 billion MIPS instructions by a compiler; the MIPS processor is implemented such that each instruction completes in an average of 1.5 cycles and the clock speed is 1 GHz

• The same program is converted into 2 billion x86 instructions; the x86 processor is implemented such that each instruction completes in an average of 6 cycles and the clock speed is 1.5 GHz
Power and Energy

• Total power = dynamic power + leakage power

• Dynamic power $\propto$ activity $\times$ capacitance $\times$ voltage$^2$ $\times$ frequency

• Leakage power $\propto$ voltage

• Energy = power $\times$ time
  (joules) (watts) (sec)

• For a CPU-bound program,
  Execution time $\propto$ cycle time $\propto$ 1 / clock speed
Example Problem

• A 1 GHz processor takes 100 seconds to execute a CPU-bound program, while consuming 70 W of dynamic power and 30 W of leakage power. Does the program consume less energy in Turbo boost mode when the frequency is increased to 1.2 GHz?
Example Problem

- A 1 GHz processor takes 100 seconds to execute a CPU-bound program, while consuming 70 W of dynamic power and 30 W of leakage power. Does the program consume less energy in Turbo boost mode when the frequency is increased to 1.2 GHz?

Normal mode energy = 100 W \times 100 \text{s} = 10,000 \text{ J}
Turbo mode energy = (70 \times 1.2 + 30) \times 100/1.2 = 9,500 \text{ J}

Note:
Frequency only impacts dynamic power, not leakage power.
We assume that the program’s CPI is unchanged when frequency is changed, i.e., exec time varies linearly with cycle time.
Benchmark Suites

• Each vendor announces a SPEC rating for their system
  ▪ a measure of execution time for a fixed collection of programs
  ▪ is a function of a specific CPU, memory system, IO system, operating system, compiler
  ▪ enables easy comparison of different systems

The key is coming up with a collection of relevant programs
SPEC CPU

• SPEC: System Performance Evaluation Corporation, an industry consortium that creates a collection of relevant programs

• SPEC 2006 includes 12 integer and 17 floating-point applications

• The SPEC rating specifies how much faster a system is, compared to a baseline machine – a system with SPEC rating 600 is 1.5 times faster than a system with SPEC rating 400

• Note that this rating incorporates the behavior of all 29 programs – this may not necessarily predict performance for your favorite program!

• Latest version: SPEC 2017
Deriving a Single Performance Number

How is the performance of 29 different apps compressed into a single performance number?

• SPEC uses geometric mean (GM) – the execution time of each program is multiplied and the N\textsuperscript{th} root is derived

• Another popular metric is arithmetic mean (AM) – the average of each program’s execution time

• Weighted arithmetic mean – the execution times of some programs are weighted to balance priorities
Amdahl’s Law

• Architecture design is very bottleneck-driven – make the common case fast, do not waste resources on a component that has little impact on overall performance/power

• Amdahl’s Law: performance improvements through an enhancement is limited by the fraction of time the enhancement comes into play

• Example: a web server spends 40% of time in the CPU and 60% of time doing I/O – a new processor that is ten times faster results in a 36% reduction in execution time (speedup of 1.56) – Amdahl’s Law states that maximum execution time reduction is 40% (max speedup of 1.66)
Common Principles

• Amdahl’s Law

• Energy: performance improvements typically also result in energy improvements – less leakage

• 90-10 rule: 10% of the program accounts for 90% of execution time

• Principle of locality: the same data/code will be used again (temporal locality), nearby data/code will be touched next (spatial locality)
Recap

• Knowledge of hardware improves software quality: compilers, OS, threaded programs, memory management

• Important trends: growing transistors, move to multi-core and accelerators, slowing rate of performance improvement, power/thermal constraints, long memory/disk latencies

• Reasoning about performance: clock speeds, CPI, benchmark suites, performance and power equations

• Next: assembly instructions
Instruction Set

• Understanding the language of the hardware is key to understanding the hardware/software interface

• A program (in say, C) is compiled into an executable that is composed of machine instructions – this executable must also run on future machines – for example, each Intel processor reads in the same x86 instructions, but each processor handles instructions differently

• Java programs are converted into portable bytecode that is converted into machine instructions during execution (just-in-time compilation)

• What are important design principles when defining the instruction set architecture (ISA)?
A Basic MIPS Instruction

C code: 
\[
a = b + c;
\]

Assembly code: (human-friendly machine instructions)
```
add   a, b, c      # a is the sum of b and c
```

Machine code: (hardware-friendly machine instructions)
```
00000100011001001000000000100000
```

Translate the following C code into assembly code:
```
a = b + c + d + e;
```
